2 Introduction

This document describes the API to MPLib, allowing you to use MPLib in your own applications. One such application is writing bindings to interface with other programming languages. The bindings to the Lua scripting language is part of the MPLib distribution and also covered by this manual.

This is a first draft of both this document as well as the API, so there may be errors or omissions in this document or strangenesses in the API. If you believe something can be improved, please do not hesitate to let us know. The contact email address is metapost@tug.org.

The C paragraphs in this document assume you understand C code, the Lua paragraphs assume you understand Lua code, and familiarity with MetaPost is assumed throughout.

2.1 Simple MPLib use

There are two different approaches possible when running MPLib. The first method is most suitable for programs that function as a command-line frontend. It uses ‘normal’ MetaPost interface with I/O to and from files, and needs very little setup to run. On the other hand, it also gives almost no chance to control the MPLib behaviour.

Here is a C language example of how to do this:

```
#include <stdlib.h>
#include "mplib.h"
int main (int argc, char **argv) {
    MP mp;
    MP_options *opt = mp_options();
    opt->command_line = argv[1];
    mp = mp_initialize(opt);
    if (mp) {
        int history = mp_run(mp);
        mp_finish(mp);
        exit (history);
    } else {
        exit (EXIT_FAILURE);
    }
}
```

This example will run in ‘inimpost’ mode.

2.2 Embedded MPLib use

The second method does not run a file, but instead repeatedly executes chunks of MetaPost language input that are passed to the library as strings, with the output redirected to internal buffers instead of directly to files.

Here is an example of how this second approach works, now using the Lua bindings:

```
local mplib = require('mplib')
local mp = mplib.new ({ ini_version = false,
                       mem_name     = 'plain' })
if mp then
    local l = mp:execute([[beginfig(1);
```

```

        fill fullcircle scaled 20;
        endfig;
    ]])
if l and l.fig and l.fig[1] then
    print (l.fig[1]:postscript())
end
mp:finish();
end

```

This example loads a previously generated ‘plain’ mem file.

3 C API for core MPlib

All of the types, structures, enumerations and functions that are described in this section are defined in the header file `mplib.h`.

3.1 Structures

3.1.1 MP_options

This is a structure that contains the configurable parameters for a new MPlib instance. Because MetaPost differentiates between `-ini` and `non-ini` modes, there are three types of settings: Those that apply in both cases, and those that apply in only one of those cases.

int	<code>ini_version</code>	1	set this to zero if you want to load a mem file.
int	<code>error_line</code>	79	maximal length of error message lines
int	<code>half_error_line</code>	50	halfway break point for error contexts
int	<code>max_print_line</code>	100	maximal length of file output
unsigned	<code>hash_size</code>	16384	size of the internal hash (always a multiple of 2). ignored in <code>non-ini</code> mode, read from mem file
int	<code>param_size</code>	150	number of simultaneously active macro parameters. ignored in <code>non-ini</code> mode, read from mem file
int	<code>max_in_open</code>	10	maximum level of <code>input</code> nesting. ignored in <code>non-ini</code> mode, read from mem file
int	<code>main_memory</code>	5000	size of the main memory array in 8-byte words; in <code>non-ini</code> mode only used if larger than the value stored in the mem file
void *	<code>userdata</code>	NULL	for your personal use only, not used by the library
char *	<code>banner</code>	NULL	string to use instead of default banner
int	<code>print_found_names</code>	0	controls whether the asked name or the actual found name of the file is used in messages
int	<code>file_line_error_style</code>	0	when this option is nonzero, the library will use <code>file:line:error</code> style formatting

			for error messages that occur while reading from input files
char *	command_line	NULL	input file name and rest of command line; only used by <code>mp_run</code> interface
int	interaction	0	explicit <code>mp_interaction_mode</code> (see below)
int	noninteractive	0	set this nonzero to suppress user interaction, only sensible if you want to use <code>mp_execute</code>
int	random_seed	0	set this nonzero to force a specific random seed
int	troff_mode	0	set this nonzero to initialize 'troffmode'
char *	mem_name	NULL	explicit mem name to use instead of <code>plain.mem</code> . ignored in <code>-ini</code> mode.
char *	job_name	NULL	explicit job name to use instead of first input file
<code>mp_file_finder</code>	<code>find_file</code>	NULL	function called for finding files
<code>mp_editor_cmd</code>	<code>run_editor</code>	NULL	function called after 'E' error response
<code>mp_makempx_cmd</code>	<code>run_make_mpx</code>	NULL	function called for the creation of mpx files

To create an `MP_options` structure, you have to use the `mp_options()` function.

3.1.2 MP

This type is an opaque pointer to a MPlib instance, it is what you have pass along as the first argument to (almost) all the MPlib functions. The actual C structure it points to has hundreds of fields, but you should not use any of those directly. All confuration is done via the `MP_options` structure, and there are accessor functions for the fields that can be read out.

3.1.3 mp_run_data

When the MPlib instance is not interactive, any output is redirect to this structure. There are a few string output streams, and a linked list of output images.

<code>mp_stream</code>	<code>term_out</code>	holds the terminal output
<code>mp_stream</code>	<code>error_out</code>	holds error messages
<code>mp_stream</code>	<code>log_out</code>	holds the log output
<code>mp_edge_object *</code>	<code>edges</code>	linked list of generated pictures

`term_out` is equivalent to `stdout` in interactive use, and `error_out` is equivalent to `stderr`. The `error_out` is currently only used for memory allocation errors, the MetaPost error messages are written to `term_out` (and are often duplicated to `log_out` as well).

You need to include `mplibps.h` to be able to actually make use this list of images, see the next section for the details on `mp_edge_object` lists.

See next paragraph for `mp_stream`.

3.1.4 mp_stream

This contains the data for a stream as well as some internal bookkeeping variables. The fields that are of interest to you are:

size_t size the internal buffer size
char * data the actual data.

There is nothing in the stream unless the `size` field is nonzero. There will not be embedded zeroes in `data`.

If `size` is nonzero, `strlen(data)` is guaranteed to be less than that, and may be as low as zero (if MPLib has written an empty string).

3.2 Function prototype typedefs

The following three function prototypes define functions that you can pass to MPLib insert the `MP_options` structure.

3.2.1 `char * (*mp_file_finder) (MP, const char*, const char*, int)`

MPLib calls this function whenever it needs to find a file. If you do not set up the matching option field (`MP_options.find_file`), MPLib will only be able to find files in the current directory.

The three function arguments are the requested file name, the file mode (either "r" or "w"), and the file type (an `mp_filetype`, see below).

The return value is a new string indicating the disk file name to be used, or NULL if the named file can not be found. If the mode is "w", it is usually best to simply return a copy of the first argument.

3.2.2 `void (*mp_editor_cmd) (MP, char*, int)`

This function is executed when a user has pressed 'E' as reply to an MetaPost error, so it will only ever be called when MPLib in interactive mode. The function arguments are the file name and the line number. When this function is called, any open files are already closed.

3.2.3 `int (*mp_makempx_cmd) (MP, char*, char *)`

This function is executed when there is a need to start generating an `mpx` file because (the first time a `btex` command was encountered in the current input file).

The first arguments is the input file name. This is the name that was given in the MetaPost language, so it may not be the same as name of the actual file that is being used, depending on how you your `mp_file_finder` function behaves. The second argument is the requested output name for `mpx` commands.

A zero return value indicates success, everything else indicates failure to create a proper `mpx` file and will result in an MetaPost error.

3.3 Enumerations

3.3.1 `mp_filetype`

The `mp_file_finder` receives an `int` argument that is one of the following types:

<code>mp_filetype_program</code>	Metapost language code (r)
<code>mp_filetype_log</code>	Log output (w)

<code>mp_filetype_postscript</code>	PostScript output (w)
<code>mp_filetype_memfile</code>	Mem file (r+w)
<code>mp_filetype_metrics</code>	TeX font metric file (r+w)
<code>mp_filetype_fontmap</code>	Font map file (r)
<code>mp_filetype_font</code>	Font PFB file (r)
<code>mp_filetype_encoding</code>	Font encoding file (r)
<code>mp_filetype_text</code>	<code>readfrom</code> and <code>write</code> files (r+w)

3.3.2 `mp_interaction_mode`

When `noninteractive` is zero, MPlib normally starts in a mode where it reports every error, stops and asks the user for input. This initial mode can be overruled by using one of the following:

<code>mp_batch_mode</code>	as with <code>batchmode</code>
<code>mp_nonstop_mode</code>	as with <code>nonstopmode</code>
<code>mp_scroll_mode</code>	as with <code>scrollmode</code>
<code>mp_error_stop_mode</code>	as with <code>errorstopmode</code>

3.3.3 `mp_history_state`

These are set depending on the current state of the interpreter.

<code>mp_spotless</code>	still clean as a whistle
<code>mp_warning_issued</code>	a warning was issued or something was <code>show-ed</code>
<code>mp_error_message_issued</code>	an error has been reported
<code>mp_fatal_error_stop</code>	termination was premature due to error(s)
<code>mp_system_error_stop</code>	termination was premature due to disaster (out of system memory)

3.3.4 `mp_color_model`

Graphical objects always have a color model attached to them.

<code>mp_no_model</code>	as with <code>withoutcolor</code>
<code>mp_grey_model</code>	as with <code>withgreycolor</code>
<code>mp_rgb_model</code>	as with <code>withrgbcolor</code>
<code>mp_cmyk_model</code>	as with <code>withcmykcolor</code>

3.3.5 `mp_knot_type`

Knots can have left and right types depending on their current status. By the time you see them in the output, they are usually either `mp_explicit` or `mp_endpoint`, but here is the full list:

```
mp_endpoint
mp_explicit
mp_given
mp_curl
mp_open
mp_end_cycle
```

3.3.6 mp_knot_originator

Knots can originate from two sources: they can be explicitly given by the user, or they can be created by the MPLib program code (for example as result of the `makepath` operator).

`mp_program_code`
`mp_metapost_user`

3.3.7 mp_graphical_object_code

There are eight different graphical object types.

<code>mp_fill_code</code>	<code>addto contour</code>
<code>mp_stroked_code</code>	<code>addto doublepath</code>
<code>mp_text_code</code>	<code>addto also (via infont)</code>
<code>mp_start_clip_code</code>	<code>clip</code>
<code>mp_start_bounds_code</code>	
<code>mp_stop_clip_code</code>	<code>setbounds</code>
<code>mp_stop_bounds_code</code>	
<code>mp_special_code</code>	<code>special</code>

3.4 Functions

3.4.1 `char *mp_metapost_version(void)`

Returns a copy of the MPLib version string.

3.4.2 `MP_options *mp_options(void)`

Returns a properly initialized option structure, or NULL in case of allocation errors.

3.4.3 `MP mp_initialize(MP_options *opt)`

Returns a pointer to a new MPLib instance, or NULL if initialisation failed. String options are copied, so you can free any of those (and the `opt` structure) immediately after the call to this function.

3.4.4 `int mp_status(MP mp)`

Returns the current value of the interpreter error state, as a `mp_history_state`. This function is useful after `mp_initialize`.

3.4.5 `int mp_run(MP mp)`

Runs the MPLib instance using the `command_line` and other items from the `MP_options`. After the call to `mp_run`, the MPLib instance should be closed off by calling `mp_finish`. The return value is the current `mp_history_state`

3.4.6 void *mp_userdata(MP mp)

Simply returns the pointer that was passed along as `userdata` in the `MP_options` struct.

3.4.7 int mp_troff_mode(MP mp)

Returns the value of `troff_mode` as copied from the `MP_options` struct.

3.4.8 mp_run_data *mp_rundata(MP mp)

Returns the information collected during the previous call to `mp_execute`.

3.4.9 int mp_execute(MP mp, char *s, size_t l)

Executes string `s` with length `l` in the MPlib instance. This call can be repeated as often as is needed. The return value is the current `mp_history_state`. To get at the produced results, call `mp_rundata`.

3.4.10 void mp_finish(MP mp)

This finishes off the use of the MPlib instance: it closes all files and frees all the memory allocated by this instance.

3.4.11 double mp_get_char_dimension(MP mp, char*fname, int n, int t)

This is a helper function that returns one of the dimensions of glyph `n` in font `fname` as a double in PostScript (AFM) units. The requested item `t` can be `'w'` (width), `'h'` (height), or `'d'` (depth).

3.4.12 int mp_memory_usage(MP mp)

Returns the current memory usage of this instance.

3.4.13 int mp_hash_usage(MP mp)

Returns the current hash usage of this instance.

3.4.14 int mp_param_usage(MP mp)

Returns the current simultaneous macro parameter usage of this instance.

3.4.15 int mp_open_usage(MP mp)

Returns the current input levels of this instance.

4 C API for graphical backend functions

These are all defined in `mplibps.h`

Unless otherwise stated, the `int` fields that express MetaPost values should be interpreted as scaled points: the 32bits are divided into an integer part and a fraction part so that the value 65536 equals 1 PostScript point (of which there are exactly 72 in an inch).

4.1 Structures

The structures in this section are used by the items in the body of the `edges` field of an `mp_rundata` structure. They are presented here in a bottom-up manner.

4.1.1 `mp_knot`

Each MPlib path (a sequence of MetaPost points) is represented as a linked list of structures of the type `mp_knot`.

<code>struct mp_knot *</code>	<code>next</code>	the next knot, or NULL
<code>mp_knot_type</code>	<code>left_type</code>	the <code>mp_knot_type</code> for the left side
<code>mp_knot_type</code>	<code>right_type</code>	the <code>mp_knot_type</code> for the right side
signed int	<code>x_coord</code>	x
signed int	<code>y_coord</code>	y
signed int	<code>left_x</code>	x of the left (incoming) control point
signed int	<code>left_y</code>	y of the left (incoming) control point
signed int	<code>right_x</code>	x of the right (outgoing) control point
signed int	<code>right_y</code>	y of the right (outgoing) control point
<code>mp_knot_originator</code>	<code>originator</code>	the <code>mp_knot_originator</code>

4.1.2 `mp_color`

The graphical object that can be colored, have two fields to define the color: one for the color model and one for the color values. The structure for the color values is defined as follows:

<code>int a_val</code>	see below, values are in scaled points
<code>int b_val</code>	-
<code>int c_val</code>	-
<code>int d_val</code>	-

All graphical objects that have `mp_color` fields also have `mp_color_model` fields. The color model decides the meaning of the four data fields:

color model value	<code>a_val</code>	<code>b_val</code>	<code>c_val</code>	<code>d_val</code>
<code>mp_no_model</code>	-	-	-	-
<code>mp_grey_model</code>	grey	-	-	-
<code>mp_rgb_model</code>	red	green	blue	
<code>mp_cmyk_model</code>	cyan	magenta	yellow	black

4.1.3 `mp_dash_object`

Dash lists are represented like this:

int * array an array of dash lengths, terminated by `-1`. the values are in scaled points
 int offset the dash array offset (as in PostScript)

4.1.4 mp_graphic_object

Now follow the structure definitions of the objects that can appear inside a figure (this is called an ‘edge structure’ in the internal WEB documentation).

There are eight different graphical object types, but there are seven different C structures. Type `mp_graphic_object` represents the base line of graphical object types. It has only two fields:

```
mp_graphical_object_code  type
struct mp_graphic_object * next  next object or NULL
```

Because every graphical object has at least these two types, the body of a picture is represented as a linked list of `mp_graphic_object` items. Each object in turn can then be typecast to the proper type depending on its `type`.

The two ‘missing’ objects in the explanations below are the ones that match `mp_stop_clip_code` and `mp_stop_bounds_code`: these have no extra fields besides `type` and `next`.

4.1.5 mp_fill_object

Contains the following fields on top of the ones defined by `mp_graphic_object`:

char *	<code>pre_script</code>	this is the result of <code>withprescript</code>
char *	<code>post_script</code>	this is the result of <code>withpostscript</code>
mp_color	<code>color</code>	the color value of this object
mp_color_model	<code>color_model</code>	the color model
unsigned char	<code>ljoin</code>	the line join style; values have the same meaning as in PostScript: 0 for mitered, 1 for round, 2 for beveled.
mp_knot *	<code>path_p</code>	the (always cyclic) path
mp_knot *	<code>htap_p</code>	a possible reversed path (see below)
mp_knot *	<code>pen_p</code>	a possible pen (see below)
int	<code>miterlim</code>	the miter limit

Even though this object is called an `mp_fill_object`, it can be the result of both `fill` and `filldraw` in the MetaPost input. This means that there can be a pen involved as well. The final output should behave as follows:

- If there is no `pen_p`; simply fill `path_p`.
- If there is a one-knot pen (`pen_p->next = pen_p`) then fill `path_p` and also draw `path_p` with the `pen_p`. Do not forget to take `ljoin` and `miterlim` into account when drawing with the pen.
- If there is a more complex pen (`pen_p->next != pen_p`) then its path has already been pre-processed for you. fill `path_p` and `htap_p`.

4.1.6 mp_stroked_object

Contains the following fields on top of the ones defined by `mp_graphic_object`:

char *	pre_script	this is the result of <code>withprescript</code>
char *	post_script	this is the result of <code>withpostscript</code>
mp_color	color	color value
mp_color_model	color_model	color model
unsigned char	ljoin	the line join style
unsigned char	lcap	the line cap style; values have the same meaning as in PostScript: 0 for butt ends, 1 for round ends, 2 for projecting ends.
mp_knot *	path_p	the path
mp_knot *	pen_p	the pen
int	miterlim	miter limit
mp_dash_object *	dash_p	a possible dash list

4.1.7 mp_text_object

Contains the following fields on top of the ones defined by `mp_graphic_object`:

char *	pre_script	this is the result of <code>withprescript</code>
char *	post_script	this is the result of <code>withpostscript</code>
mp_color	color	color value
mp_color_model	color_model	color model
char *	text_p	string to be placed
char *	font_name	the MetaPost font name
unsigned int	font_dsize	size of the font
int	width	width of the picture resulting from the string
int	height	height
int	depth	depth
int	tx	transformation component
int	ty	transformation component
int	txx	transformation component
int	tyx	transformation component
int	txy	transformation component
int	tyy	transformation component

All fonts are loaded by MPlib at the design size (but not all fonts have the same design size). If text is to be scaled, this happens via the transformation components.

4.1.8 mp_clip_object

Contains the following field on top of the ones defined by `mp_graphic_object`:

mp_knot *	path_p	defines the clipping path that is in effect until the object with the matching <code>mp_stop_clip_code</code> is encountered
-----------	--------	--

4.1.9 mp_bounds_object

Contains the following field on top of the ones defined by `mp_graphic_object`:

`mp_knot *` `path_p` the path that was used for boundary calculation

This object can be ignored when output is generated, it only has effect on the boundingbox of the following objects and that has been taken into account already.

4.1.10 `mp_special_object`

This represents the output generated by a MetaPost `special` command. It contains the following field on top of the ones defined by `mp_graphic_object`:

`char *` `pre_script` the special string

Each `special` command generates one object. All of the relevant `mp_special_objects` for a figure are linked together at the start of that figure.

4.1.11 `mp_edge_object`

<code>mp_edge_object *</code>	<code>next</code>	points to the next figure (or NULL)
<code>mp_graphic_object *</code>	<code>body</code>	a linked list of objects in this figure
<code>char *</code>	<code>filename</code>	this would have been the used filename if a PostScript file would have been generated
<code>MP</code>	<code>parent</code>	a pointer to the instance that created this figure
<code>int</code>	<code>minx</code>	lower-left x of the bounding box
<code>int</code>	<code>miny</code>	lower-left y of the bounding box
<code>int</code>	<code>maxx</code>	upper right x of the bounding box
<code>int</code>	<code>maxy</code>	upper right y of the bounding box
<code>int</code>	<code>width</code>	value of <code>charwd</code> ; this would become the TFM width (but without the potential rounding correction for TFM file format)
<code>int</code>	<code>height</code>	similar for height (<code>charht</code>)
<code>int</code>	<code>depth</code>	similar for depth (<code>chardp</code>)
<code>int</code>	<code>ital_corr</code>	similar for italic correction (<code>charic</code>)
<code>int</code>	<code>charcode</code>	Value of <code>charcode</code> (rounded, but not modulated for TFM's 256 values yet)

4.2 Functions

4.2.1 `int mp_ps_ship_out(mp_edge_object*hh,int prologues,int procset)`

If you have an `mp_edge_object`, you can call this function. It will generate the PostScript output for the figure and save it internally. A subsequent call to `mp_rundata` will find the generated text in the `ps_out` field.

Returns zero for success.

4.2.2 `void mp_gr_toss_objects(mp_edge_object*hh)`

This frees a single `mp_edge_object` and its `mp_graphic_object` contents.

4.2.3 void mp_gr_toss_object(mp_graphic_object*p)

This frees a single mp_graphic_object object.

4.2.4 mp_graphic_object *mp_gr_copy_object(MP mp, mp_graphic_object*p)

This creates a deep copy of a mp_graphic_object object.

5 C API for label generation (a.k.a. makempx)

The following are all defined in mpxout.h.

5.1 Structures

5.1.1 MPX

An opaque pointer that is passed on to the file_finder.

5.1.2 mpx_options

This structure holds the option fields for mpx generation. You have to fill in all fields except mptexpre, that one defaults to mptexpre.tex

mpx_modes	mode	
char *	cmd	the command (or sequence of commands) to run
char *	mptexpre	prepended to the generated T _E X file
char *	mpname	input file name
char *	mpxname	output file name
char *	banner	string to be printed to the generated to-be-typeset file
int	debug	When nonzero, mp_makempx outputs some debug information and do not delete temp files
mpx_file_finder	find_file	

5.2 Function prototype typedefs

5.2.1 char * (*mpx_file_finder) (MPX, const char*, const char*, int)

The return value is a new string indicating the disk file to be used. The arguments are the file name, the file mode (either "r" or "w"), and the file type (an mpx_filetype, see below). If the mode is "w", it is usually best to simply return a copy of the first argument.

5.3 Enumerations

5.3.1 mpx_modes

mpx_tex_mode
mpx_troff_mode

5.3.2 mpx_filetype

mpx_tfm_format	T _E X or Troff font metric file
mpx_vf_format	T _E X virtual font file
mpx_trfontmap_format	Troff font map
mpx_trcharadj_format	Troff character shift information
mpx_desc_format	Troff DESC file
mpx_fontdesc_format	Troff FONTDESC file
mpx_specchar_format	Troff special character definition

5.4 Functions

5.4.1 `int mpx_makempx(mpx_options *mpxopt)`

A return value of zero is success, non-zero values indicate errors.

6 Lua API

The MetaPost library interface registers itself in the table `mplib`.

6.1 `mplib.version`

Returns the MPlib version.

```
<string> s = mpplib.version()
```

6.2 `mplib.new`

To create a new metapost instance, call

```
<mpinstance> mp = mpplib.new({...})
```

This creates the `mp` instance object. The argument hash can have a number of different fields, as follows:

name	type	description	default
<code>error_line</code>	number	error line width	79
<code>print_line</code>	number	line length in ps output	100
<code>main_memory</code>	number	total memory size	5000
<code>hash_size</code>	number	hash size	16384
<code>param_size</code>	number	max. active macro parameters	150
<code>max_in_open</code>	number	max. input file nestings	10
<code>random_seed</code>	number	the initial random seed	variable
<code>interaction</code>	string	the interaction mode, one of <code>batch</code> , <code>nonstop</code> , <code>scroll</code> , <code>errorstop</code>	<code>errorstop</code>
<code>ini_version</code>	boolean	the <code>-ini</code> switch	<code>true</code>
<code>mem_name</code>	string	<code>-mem</code>	<code>plain</code>
<code>job_name</code>	string	<code>-jobname</code>	<code>mpout</code>
<code>find_file</code>	function	a function to find files	only local files

The `find_file` function should be of this form:

```
<string> found = finder (<string> name, <string> mode, <string> type)
```

with:

name the requested file

mode the file mode: `r` or `w`

type the kind of file, one of: `mp`, `mem`, `tfm`, `map`, `pfb`, `enc`

Return either the full pathname of the found file, or `nil` if the file cannot be found.

6.3 `mp:statistics`

You can request statistics with:

```
<table> stats = mp:statistics()
```

This function returns the vital statistics for an MPLib instance. There are four fields, giving the maximum number of used items in each of the four statically allocated object classes:

```
main_memory  number  memory size
hash_size    number  hash size
param_size   number  simultaneous macro parameters
max_in_open  number  input file nesting levels
```

6.4 mp:execute

You can ask the METAPOST interpreter to run a chunk of code by calling

```
local rettable = mp:execute('metapost language chunk')
```

for various bits of Metapost language input. Be sure to check the `rettable.status` (see below) because when a fatal METAPOST error occurs the MPLib instance will become unusable thereafter. Generally speaking, it is best to keep your chunks small, but beware that all chunks have to obey proper syntax, like each of them is a small file. For instance, you cannot split a single statement over multiple chunks.

In contrast with the normal standalone `mpost` command, there is *no* implied 'input' at the start of the first chunk.

6.5 mp:finish

```
local rettable = mp:finish()
```

If for some reason you want to stop using an MPLib instance while processing is not yet actually done, you can call `mp:finish`. Eventually, used memory will be freed and open files will be closed by the Lua garbage collector, but an explicit `mp:finish` is the only way to capture the final part of the output streams.

6.6 Result table

The return value of `mp:execute` and `mp:finish` is a table with a few possible keys (only `status` is always guaranteed to be present).

```
log    string  output to the 'log' stream
term   string  output to the 'term' stream
error  string  output to the 'error' stream (only used for 'out of memory')
status number  the return value: 0=good, 1=warning, 2=errors, 3=fatal error
fig    table   an array of generated figures (if any)
```

When `status` equals 3, you should stop using this MPLib instance immediately, it is no longer capable of processing input.

If it is present, each of the entries in the `fig` array is a userdata representing a figure object, and each of those has a number of object methods you can call:

```
boundingbox  function  returns the bounding box, as an array of 4 values
postscript   function  return a string that is the ps output of the fig
```

svg	function	return a string that is the svg output of the <code>fig</code>
objects	function	returns the actual array of graphic objects in this <code>fig</code>
copy_objects	function	returns a deep copy of the array of graphic objects in this <code>fig</code>
filename	function	the filename this <code>fig</code> 's PostScript output would have written to in stand-alone mode
width	function	the <code>charwd</code> value
height	function	the <code>charht</code> value
depth	function	the <code>chardp</code> value
italcorr	function	the <code>charic</code> value
charcode	function	the (rounded) <code>charcode</code> value

NOTE: you can call `fig:objects()` only once for any one `fig` object!

When the boundingbox represents a 'negated rectangle', i.e. when the first set of coordinates is larger than the second set, the picture is empty.

Graphical objects come in various types that each have a different list of accessible values. The types are: `fill`, `outline`, `text`, `start_clip`, `stop_clip`, `start_bounds`, `stop_bounds`, `special`. There is helper function (`mplib.fields(obj)`) to get the list of accessible values for a particular object, but you can just as easily use the tables given below).

All graphical objects have a field `type` that gives the object type as a string value, that not explicit mentioned in the tables. In the following, numbers are PostScript points represented as a floating point number, unless stated otherwise. Field values that are of `table` are explained in the next section.

6.6.1 fill

path	table	the list of knots
htap	table	the list of knots for the reversed trajectory
pen	table	knots of the pen
color	table	the object's color
linejoin	number	line join style (bare number)
miterlimit	number	miter limit
prescript	string	the prescript text
postscript	string	the postscript text

The entries `htap` and `pen` are optional.

There is helper function (`mplib.pen_info(obj)`) that returns a table containing a bunch of vital characteristics of the used pen (all values are floats):

width	number	width of the pen
rx	number	x scale
sx	number	xy multiplier
sy	number	yx multiplier
ry	number	y scale
tx	number	x offset
ty	number	y offset

6.6.2 outline

path	table	the list of knots
pen	table	knots of the pen

color	table	the object's color
linejoin	number	line join style (bare number)
miterlimit	number	miter limit
linecap	number	line cap style (bare number)
dash	table	representation of a dash list
prescript	string	the prescript text
postscript	string	the postscript text

The entry `dash` is optional.

6.6.3 text

text	string	the text
font	string	font tfm name
dsize	number	font size
color	table	the object's color
width	number	
height	number	
depth	number	
transform	table	a text transformation
prescript	string	the prescript text
postscript	string	the postscript text

6.6.4 special

prescript	string	special text
-----------	--------	--------------

6.6.5 start_bounds, start_clip

path	table	the list of knots
------	-------	-------------------

6.6.6 stop_bounds, stop_clip

Here are no fields available.

6.7 Subsidiary table formats

6.7.1 Paths and pens

Paths and pens (that are really just a special type of paths as far as MPlib is concerned) are represented by an array where each entry is a table that represents a knot.

<code>left_type</code>	string	when present: 'endpoint', but usually absent
<code>right_type</code>	string	like <code>left_type</code>
<code>x_coord</code>	number	x coordinate of this knot
<code>y_coord</code>	number	y coordinate of this knot
<code>left_x</code>	number	x coordinate of the precontrol point of this knot

left_y number y coordinate of the precontrol point of this knot
right_x number x coordinate of the postcontrol point of this knot
right_y number y coordinate of the postcontrol point of this knot

There is one special case: pens that are (possibly transformed) ellipses have an extra string-valued key **type** with value **elliptical** besides the array part containing the knot list.

6.7.2 Colors

A color is an integer array with 0, 1, 3 or 4 values:

0 marking only no values
 1 greyscale one value in the range (0,1), 'black' is 0
 3 RGB three values in the range (0,1), 'black' is 0,0,0
 4 CMYK four values in the range (0,1), 'black' is 0,0,0,1

If the color model of the internal object was **uninitialized**, then it was initialized to the values representing 'black' in the colorspace **defaultcolormodel** that was in effect at the time of the **shipout**.

6.7.3 Transforms

Each transform is a six-item array.

1 number represents x
 2 number represents y
 3 number represents xx
 4 number represents yx
 5 number represents xy
 6 number represents yy

Note that the translation (index 1 and 2) comes first. This differs from the ordering in PostScript, where the translation comes last.

6.7.4 Dashes

Each **dash** is two-item hash, using the same model as PostScript for the representation of the dashlist. **dashes** is an array of 'on' and 'off', values, and **offset** is the phase of the pattern.

dashes hash an array of on-off numbers
offset number the starting offset value

6.8 Character size information

These functions find the size of a glyph in a defined font. The **fontname** is the same name as the argument to **infont**; the **char** is a glyph id in the range 0 to 255; the returned **w** is in AFM units.

6.8.1 mp.char_width

<number> w = mp.char_width(<string> fontname, <number> char)

6.8.2 mp.char_height

```
<number> w = mp.char_height(<string> fontname, <number> char)
```

6.8.3 mp.char_depth

```
<number> w = mp.char_depth(<string> fontname, <number> char)
```
