

# The package `parese`<sup>\*†</sup>

Le T<sub>E</sub>Xnicien de surface  
[le.texnicien.de.surface@wanadoo.fr](mailto:le.texnicien.de.surface@wanadoo.fr)

April 20, 2011

## Abstract

This package implements an example from T. LACHAND-ROBERT in [1]. It provides a means of typing isolated greek letters with the character § activated and redefined. Instead of `\(\alpha\)` one types `§a` to obtain  $\alpha$ .

## Résumé

La documentation française pour l'utilisateur de l'extension `parese` est désormais disponible sous le nom de `parese-fr.pdf`.  
Le fichier `parese.pdf` contient le code commenté en anglais.

†English translation by the author. Any comment about the translation is welcome.

## 1 Introduction

This package provides only a ‘quick and low-cost’ access to greek letters which one can obtain with a macro such as `\alpha` or `\Omega`. It provides also an environment and a macro which make possible the use of `§` to type in those letters. Because of an `\ensuremath` we are not bound to explicitly enter —i.e. by typing `§ §` or `\( \)` or else `\[ \]` or anything whatsoever with the same effect— mathematics mode to obtain a greek letter.

The idea of the method is from T. LACHAND-ROBERT and described in [1]. I have just add the `\ensuremath` which is so agreeable to write macros.

There is *no* macros for the lowercase omicron nor for the uppercase alpha, beta... that one can obtain with the latin roman letters with the same look. I have not had the courage nor the strength to build a solution which would provide a means of obtaining an upright uppercase alpha in a math formula embedded in an italic boldfaced text.

Even if the meaning of the French ‘paresse’ is just ‘lazyness’ I would like to emphasize that the name of this package comes from the fact that the sign `§` can be used to point at a paragraph and looks like an S. So there is no connection between the name and the not unfrequent sin of the same (French) name... or maybe...

## 2 Why a 4th Version?

I don’t remember exactly on what occasion — age, disk crash and computer mishap aiding — and even less when — more than a year ago, I’m afraid — Christian TELLECHEA wrote me that he would be glad to use `paresse` in his utf-8 encoded sources with `LATEX` — not with `XYLATEX` nor `LuaLATEX`.

We exchanged emails, Christian sent me working material. He even made me the gift of two versions, the second better for the identification of the encoding passed, as an option, to `inputenc`. However I procrastinated. My personal life and my job may have interfered with the development of this package.

At last, here is the thing.

The newest feature should escape the user of `LuaLATEX` or `XYLATEX` and even of `LATEX` loading `inputenc` with an option such as `latin1` or `latin9`. However, henceforth, one can use this package with `LATEX` loading `inputenc` with option `utf8`.

N (v4)

I take advantage of this new version to add a `§`-macro: `§Z` which produces `§`, symbol already available with `\S`, so I don’t dare to present it as a real “shortcut”.

## 3 Why a 3rd Version?

With a mail Claudio BECCARI kindly informed me that there was an encoding of the greek alphabet with latin letters some 15 years before I committed this extension. This encoding was devised by Sylvio LEVI who, at the time, was designing the first greek font for `TEX`, using the correspondance between greek and us keyboard. Claudio wrote to me, and I can’t but agree with him, that if one is used to LEVI’s encoding, one would rather keep one’s habit in order to use `paresse`.

I, then, decided to provide a new couple of mutually exclusive options: the first one is `LEGACY` with which one obtain the original encoding of this extension and which is active by default, the other one is `LEVI` which provides Sylvio LEVI's encoding.

I take advantage of this update to make some cosmetic changes: from now on all inner *secret* macros have a name which begins with `\GA@`; the `.dtx` file is reorganised to facilitate the translation of the documentation.

## 4 Usage

One loads the package with `\usepackage{paresse}` **after** the package `inputenc` when using  $\LaTeX$ . The sign  $\S$  must be recognised as a letter by  $\TeX$ . One can use for instance `inputenc` with option `latin1` for such a purpose.

**N (v4)** One will obtain the same behaviour, but for the exception pointed out on page 3, with `inputenc` and option `utf8`.

**N (v4)** There is no such restriction when one compiles with  $\text{Lua}\LaTeX$  or  $\text{Xe}\LaTeX$  a source encoded in UTF-8.

By default the package is loaded with option `wild` and so the macros such as `\Sa` are immediately available. If one prefers one can choose the option `TAME` by writing `\usepackage[tame]{paresse}`. One must then use the command `\ActiveLaParesse` or the environment `ParesseActive` to use the ‘ $\S$ -macros’.

When ‘`paresse`’ is active, one has just to type `\Sa` in to obtain  $\alpha$ . One has access, by the same means, to all the other greek letters to which a macro is devoted such as `\alpha`, see the tables 4.3.1 and 4.3.2. One obtains  $\alpha^\beta$  with `\(\Sa^\{Sb}\)` when  $\S$  is active.

One will note that the curly braces are *not* compulsory and that one obtains the same result with just `\(\Sa^Sb\)` **unless** one uses a utf-8 encoded source with  $\LaTeX$ .

### 4.1 Options

`TAME` / `WILD`

- `TAME` is the contrary of `WILD` which is the option by default. When `TAME` reigns, one **must** use an environment `ParesseActive` or a command `\ActiveLaParesse` in order to use the  $\S$ -macros.

`LEGACY` / `LEVI`

- `LEVI` is the contrary of `LEGACY` which is the default. With `LEGACY` one uses the original encoding of `paresse.sty` as it is given by the table 4.3.1. If the option `LEVI` is enforced, one uses the Sylvio LEVI encoding, see the table 4.3.2.

`TTAU` / `TTHETA`

- `TTAU` is the contrary of `TTHETA` which is selected by default. When `TTHETA` is active `\St` gives  $\theta$  in the contrary `\St` gives  $\tau$ . In all cases,  $\theta$  is given by `\Sv` and  $\tau$  by `\Sy`. That option is ineffective when one has chosen `LEVI`.

**Remark:** when one has chosen the option `LEGACY`,  $\Theta$  is ‘regularly’ obtained with `\Sv` and *also* with `\ST` whatever is the chosen option. In the case of the option `LEVI`, `\Sv` doesn't correspond to any greek letter.

`EPSILON` / `VAREPSILON`

- `EPSILON` is the contrary of `VAREPSILON` which is selected by default. With `EPSILON`, `\Se` gives  $\epsilon$  otherwise `\Se` gives  $\varepsilon$ .

- The following ‘couples’ behave as EPSILON, VAREPSILON: THETA and VARTHETA; PI and VARPI; RHO and VARRHO; SIGMA and VARSIGMA; PHI and VARPHI.

The default options are VAREPSILON, THETA, PI, RHO, SIGMA, VARPHI, WILD and LEGACY. That ensures that this 3rd version behaves, by default, as the preceding one.

## 4.2 Commands and Environment

|                                 |   |
|---------------------------------|---|
| <code>\makeparesseletter</code> | This command gives the letter-catcode to the ‘character’ §. After that one can use § in the name of a macro, for instance. It corresponds to the well-known <code>\makeatletter</code> .  |
| <code>\makeparesseother</code>  | This macro gives the catcode <i>other</i> to the character §. It is the ‘contrary’ of the preceding one. It corresponds to <code>\makeatother</code> .<br>This macro is inactivated when one uses a utf-8 encoding with L <sup>A</sup> T <sub>E</sub> X. In such a case it wouldn’t have a clear meaning. When used it issues a warning in the .log file. |
| <code>\ActiveLaParesse</code>   | This macro makes § active and thus enable one to access the macros the name of which begins with § such as §a. A list of these macros and theirs meanings is given in the tables 4.3.1 and 4.3.2.   |
| <code>ParesseActive</code>      | In this environment § is active and one can use the §-macros. One could use this environment if one want to use the §-macros when the package <code>paresse.sty</code> is loaded with the option <code>tame</code> .  |

## 4.3 Tables of the Macros

### 4.3.1 `paresse.sty`’s Original Encoding

This is the active encoding when one choses the option LEGACY which is the default.

|    |   |    |   |    |   |    |   |
|----|---|----|---|----|---|----|---|
| §a | α | §b | β | §g | γ | §d | δ |
| §e | ε | §z | ζ | §h | η | §v | θ |
| §i | ι | §k | κ | §l | λ | §m | μ |
| §n | ν | §x | ξ | §p | π | §r | ρ |
| §s | σ | §y | τ | §u | υ | §f | φ |
| §c | χ | §q | ψ | §w | ω |    |   |
| §G | Γ | §D | Δ | §V | Θ | §L | Λ |
| §X | Ξ | §P | Π | §S | Σ | §U | Υ |
| §F | Φ | §Q | Ψ | §W | Ω | §Z | § |

**Remarks :** all the latin letters used in the name of the §-macros, but for  $\theta$ ,  $\tau$  and  $\psi$ , are loaded with reminiscences, I hope :-)) and the greek uppercases are obtained with the (latin) corresponding uppercases.

### 4.3.2 Sylvio Levi's Encoding

One make this encoding active with the option LEVI.

|        |               |        |          |        |            |        |             |
|--------|---------------|--------|----------|--------|------------|--------|-------------|
| $\S a$ | $\alpha$      | $\S b$ | $\beta$  | $\S g$ | $\gamma$   | $\S d$ | $\delta$    |
| $\S e$ | $\varepsilon$ | $\S z$ | $\zeta$  | $\S h$ | $\eta$     | $\S j$ | $\theta$    |
| $\S i$ | $\iota$       | $\S k$ | $\kappa$ | $\S l$ | $\lambda$  | $\S m$ | $\mu$       |
| $\S n$ | $\nu$         | $\S x$ | $\xi$    | $\S p$ | $\pi$      | $\S r$ | $\rho$      |
| $\S s$ | $\sigma$      | $\S t$ | $\tau$   | $\S u$ | $\upsilon$ | $\S f$ | $\varphi$   |
| $\S q$ | $\chi$        | $\S y$ | $\psi$   | $\S w$ | $\omega$   | $\S c$ | $\varsigma$ |
| $\S G$ | $\Gamma$      | $\S D$ | $\Delta$ | $\S J$ | $\Theta$   | $\S L$ | $\Lambda$   |
| $\S X$ | $\Xi$         | $\S P$ | $\Pi$    | $\S S$ | $\Sigma$   | $\S U$ | $\Upsilon$  |
| $\S F$ | $\Phi$        | $\S Y$ | $\Psi$   | $\S W$ | $\Omega$   | $\S Z$ | $\xi$       |

Sylvio LEVI's encoding gives a direct acces to `\varsigma` ( $\varsigma$ ) with `\S c` and is different from the original encoding just for the letters  $\theta$ ,  $\tau$ ,  $\chi$  et  $\psi$ . Here is a summary of theses differences:

|                    |                        |                        |                   |                   |                        |                   |                   |
|--------------------|------------------------|------------------------|-------------------|-------------------|------------------------|-------------------|-------------------|
| greek letters      | $\theta$               | $\tau$                 | $\chi$            | $\psi$            | $\Theta$               | $\Psi$            | $\varsigma$       |
| original encoding  | <code>\S v/\S t</code> | <code>\S y/\S t</code> | <code>\S c</code> | <code>\S q</code> | <code>\S V/\S T</code> | <code>\S Q</code> | —                 |
| S. LEVI's encoding | <code>\S j</code>      | <code>\S t</code>      | <code>\S q</code> | <code>\S y</code> | <code>\S J</code>      | <code>\S Y</code> | <code>\S c</code> |
